Object Detection on Encrypted Data

Using Secure Multiparty Computation

Felix LERNER

Voorwoord

Het voorwoord vul je persoonlijk in met een appreciatie of dankbetuiging aan de mensen die je hebben bijgestaan tijdens het verwezenlijken van je masterproef en je hebben gesteund tijdens je studie.

Samenvatting

De (korte) samenvatting, toegankelijk voor een breed publiek, wordt in het Nederlands geschreven en bevat **maximum 3500 tekens**. Deze samenvatting moet ook verplicht opgeladen worden in KU Loket.

Abstract

We are affected with machine learning in many aspects of our daily lives, applications ranges from facial recognition to enhanced healthcare to self-driving cars. As companies outsource image classification tasks to cloud computing service providers, we see a rise in privacy concerns for both the users wishing to keep their data confidential, as for the company wishing to keep their classifier obfuscated.

Keywords: Computer vision, Cryptography, machine learning, secure multiparty computation, deep learning, object detetcion, privacy preserving, MLaaS, encryption

MPC Secure Multiparty Computation
MLaaS Machine Learning as a Service
CNN Convolutional Neural Network
ReLU Rectified Linear Unit

1
Introduction

TODO: Praten over Onespan Deep learning based object detection on images is a hot topic for researchers and interest in machine learning is steadily growing among miscellaneous businesses. Secure multiparty computation (MPC) is a subfield of cryptography, making it possible for a party to run an algortihm on confidential data, that is supposed to stay unknown even to the party running the algorithm.

Both concepts aren't new concepts, but with the rise of big data and processing power, there has been an increase in research into these fields.

In this thesis we present the applicability of MPC for deep learning based object detection.

1.1 Problem

The use of third party MLaaS (Machine Learning as a Service) providers or any cloud computing solution, as processing power for an image classification task, raises privacy concerns as sensitive images of users need to be sent to servers running an instance of the neural network. It's important to note that the transport of the image from the client to the server is secure, since the parties can make use of reliable HTTPS (Hypertext Transfer Protocol Secure) connections. The user's images, however, are stored in plaintext on the server, aswell as the computed output of the image. Furthermore the whole design of the neural network including all trained parameters needs to be stored on the servers of the third party, for the image classifier to function. Both of these remote storage solutions require a considerably amount of trust in the third party. Since the third party could potentially exploit the user data for commercial purposes or even steal the intellectual property of the image classifier. In this thesis we try to tackle the need to trust a third party MLaaS provider.

We want it to compute an encrypted image on an obfuscated neural network to ouput a correct encrypted result.

1.2 Hypothesis

How can we securely compute the forward propagation of a face recognition network?

With the use of MPC protocols we can implement methods such that we can compute a whole neural network on an encrypted input. We predict a drastically decrease in perfomance and will try to find performance optimizations along the way of implementing a proof of concept.

2

Literature study

In this chapter we will take a quick look at how convolutional neural networks function, layer by layer. We will also learn how secure multiparty computation (MPC) in general is possible. Finaly, we will show the related work on this subject so far.

2.1 Convolutional neural network

Convolution neural networks (CNN) is a special type of neural network used for images. The spatial properties of the pixels in the image are used during the evaluation of the input, meaning the neighbouring pixels of a central pixel impact the output to the next layer of that central pixel while pixels further away do not. CNNs are made of multiple layers. Typically, as you move further from the input layer to the output layer the dimensionality reduces, we can say the input gets mapped on a desired output manifold. Inputs that we classify as similar are supposed to be in the same region in the output manifold.

2.1.1 Convolution layer

In this layer a discrete convolution of a kernel K shifting over an image I is performed, as shown in equation 2.1. The kernel has parameters also called weights, so that certain features get extracted from the input.

$$(I * K)[m,n] = \sum_j \sum_k I[m-j, n-k]K[j,k] \tag{2.1}$$

The output of this layer is a convolved feature map.

2.1.2 Activation function

Since these convolutions are simple lineair operations and most image classification tasks require non-lineair classifiers, non-lineairity needs to be added to the neural network. This is achieved through adding a non-linear activation function after a convolution or fully connected layer. The most popular activation function is the rectified linear unit (ReLU) as seen in equation 2.2.

$$f(x) = max(0, 1) \tag{2.2}$$

2.1.3 Pooling layer

The dimensionality reduction we talked about in the beginning of this chapter happens in the pooling layer. A kernel is shifted over the image. In the case of max pooling the kernel selects the maximum value of the portion of the image it covers, to create the new dimensionality reduced image.

2.1.4 Fully connected layer

The fully connected layer is a multilayer perceptron that discriminates different object classes and identifies identical ones. All elements in vector h_{i-1}^{out} have their own bias B_i and weight W_i so that h_i^{in} can be calculated for each layer i according to equation 2.3.

$$h_i^{in} = h_{i-1}^{out} \cdot W_i + B_i \tag{2.3}$$

2.2 Secure multiparty computation

Secure multiparty coputation is a protocol that is used between n number of parties P. Each of these parties has private data also called a secret S. With MPC it is possible for these parties to compute a public[1] function f on the secrets. Such that a party $p_i \in P$ only knows his secret $s_i \in S$ and the public securely computed output $f(s_0, s_2, s_{n-1})$ after the protocol has succesfully finished. A classic application is Yao's Millionaires' problem Yao (1982) in wich two millionaires wish to know who is richer, there is catch however. Instead of making their balances publicly known. They wish to keep their balances a secret. In this case the number of parties n is 2 the secrets s_0 and s_1 are their balances. The public function $f(s_0, s_1) = 1$ if $s_0 < s_1$ and 0 otherwise.

We categorize 2 types of parties based on their willingness to deviate from the correct predefined protocol.

- Honest but curious parties (passive): Parties wish to know other parties secrets but will not deviate from the protocol at any time.

- Malicious parties (active): Parties wish to know other parties secrets and wish to change output of computation to favourable result. Parties will deviate from the protocol to cheat and change the outcome at any time.

---

[1]public or global means known to all parties, while private or local means known only by the corresponding party

If the two millionaires are honest but curious parties, they will not deviate from the protocol and they will computer the correct output as a result they will know who is the richer millionair but they won't know how much money the other one has. In the other case one of the two millionaires is corrupt and acts maliciously, the honest millionair will follow protocol while the dishonest millionair will deviate from the protocol to change the result in his favour. In the event that the dishonest millionair is poorer he will change the outcome thus appearing richer. From now on, we assume the parties are honest but curious parties, unless specified otherwise. We also assume the communication between the different parties to be secure.

2.2.1 Secret sharing

In order to do secure computing, the parties need to split their secret into secret shares. A secret sharing method can be used by the secret holder to split a secret into a number of shares. Combining these shares will reveal the secret, while individual shares alone will leak nothing about the secret. In a (t,n) threshold secret sharing sheme parties must combine atleast t shares of the total n shares, to obtain the secret. We can now set a threshold t high enough, denying the secret to small curious parties and allowing to reveal the secret when a majority $(\geq t)$ consensus is reached. Shamir's secret sharing scheme Shamir (1979) is based on polynomial interpolation and the essential idea is that it takes atleast t points in order to define a polynomial $p(x)$ of degree $t-1$. Given a set of t points in a 2-dimensional carthesian system $(x_1, y_1), (x_2, y_2), ..., (x_t, y_t)$, there exists only one polynomial of degree $t-1$. This can be proven and the mathematical construction of a polynomial $p(x)$ of degree $t-1$ based on a set of t points can be calculated using Lagrange's interpolation formula 2.4.

$$p(x) = \sum_{i=1}^{t} y_i \delta_i(x) \quad \text{with} \quad \delta_i(x) = \prod_{1 \leq j < t; i \neq j} \frac{x - x_i}{x_j - x_i} \tag{2.4}$$

With this in mind, a secret dealer can now share his secret s to n parties by choosing a random $t-1$ degree polynomial $p(x) = a_0 + a_1 x + ... + a_{t-1} x^{t-1}$ in which a_0 is the secret or the number representation of the secret if the secret is not a number. The dealer now calculates n points on the polynomial starting from $x = 1$, because the secret is located at $x = 0$. Each party $p_i \in p_1, p_2, ..., p_n$ is given a different single point (x_i, y_i), at this stage the secret is shared.

To recombine the secret, the parties simply broadcast or send their shares to a central entity, if more than t shares are known, it suffices to calculate the Lagrange polynomial $p(x)$ and $s = p(0)$. In the case of not having enough shares, the Lagrange polynomial containing the secret becomes impossible to calculate since every polynomial is equally likely, thus revealing absolutely nothing about the secret.

In figure 2.1 a visualisation of this scheme shows us that in order to get the secret value, 4 in this case, we need to know atleast $t+1$ points for a given t. The trivial case where $t = 0$ (green line) is simple to understand. The secret is simply the y-value of the given point. Of course this is a rather useless approach to secret sharing since you are giving away the cleartext secret. The full potential of secret sharing becomes true for cases where $t > 0$. Two points are needed for a first
Figure 2.1: Shares for different t with secret $s = 4$

order polynomial (red line), three points for a second order polynomial and so on.

It's important to make sure the parties are distributed and to try minimizing the incentive to collude. Distribution is needed to lower the risk of having a malicious party taking over control of the network, this can be done by splitting the parties up to many small stakeholders instead of a couple centralized stakeholders. We can only be sure to avoid collusion if the secret holder partakes to the MPC. This is often not desired and we are willing to take that risk.

2.2.2 Operations

A neural network can be seen as an enormous function with millions of coefficients. Lucky for us the function can be broken up into 3 different operations: addition and multiplication in fully connected and convolution layers and a relational operator for max pooling and ReLU activation function. We will now show how to securely compute each of these operations.

4.2 Discussion

4.3 Conclusion

Er zijn twee manieren om formules in LaTeX in te voeren:

- Inline: $a^2 + b^2 = c^2$ (`$a^2+b^2 = c^2$`)

- In een equation omgeving (`\begin{equation} a^2+b^2 = c^2 \end{equation}`):

$$a^2 + b^2 = c^2 \tag{4.1}$$

Griekse letters geef je in d.m.b. het backslash commando. Bijvoorbeeld de letter sigma σ verkrijg je door `$\sigma$` inline in te geven. Dit is analoog voor griekse letters in de equation omgeving. Een beknopte lijst van symbolen vind je op de Wikibooks pagina voor LaTeX (link). Alle andere nuttige informatie omtrent het gebruik van LaTeX voor formules vind je hier ook terug.

5
Conclusion

Voor het verwijzen naar informatiebronnen wordt gebruik gemaakt van het numerisch systeem of van het auteur-jaar systeem. Dit kies je door volgend commando in het latex bronbestand aan te passen:

- numerisch (IEEE) : `\bibliographystyle{ieee}`

- alfabetisch (APA) : `\bibliographystyle{apalike}`

Plaats je bronnen in een *bibtex* bestand (evt. via software zoals bv. Jabref Endnote of Mendeley), waarnaar je verwijst vanuit je thesis text a.d.h.v. het commando `\cite`. Enkele links naar nuttige software in deze context:

- JabRef (Open Source)

- Mendeley (Freeware)

- EndNote (Paid license)

Indien je zelf een .bibtex bestand wil aanleggen dien je volgende syntax te volgen voor een tijdschriftartikel:

```
@article{hughes2005,
title={Isogeometric analysis: CAD, finite elements, NURBS, exact geometry
and mesh refinement},
author={Hughes, Thomas JR and Cottrell, John A and Bazilevs, Yuri},
journal={Computer methods in applied mechanics and engineering},
volume={194},
number={39},
pages={4135--4195},
year={2005},
publisher={Elsevier}
}
```

Enkele voorbeelden van het gebruik van bronnen in een tekst (in APA stijl):

Recent werd het Higgs boson experimenteel vastgesteld door Aad et al. Aad et al. (2012) (syntax: `\cite{aad2012}`).

Als alternatief voor het discretiseren van een CAD model vooraleer een eindige elementenanalyse te kunnen toepassen, stellen Hughes et al. voor om de nodige elementenformulering rechtstreeks uit de NURBS beschrijving van de CAD geometrie te halen Hughes et al. (2005) (syntax: `\cite{hughes2005}`). Daarnaast introduceren ze tevens een k-iteratieve procedure als een verfijning van de geldende p- en h-iteratieve procedures in eindige elementen methoden Cottrell et al. (2009) (syntax: `\cite{cottrell2009}`).
